**PROTOCOL SUMMARY****Objective:**

To conduct a multi-center randomized crossover trial in six pediatric ICUs staffed by PGY2 and PGY3 residents to compare the effectiveness and safety of a sleep and circadian science-based (SCS) intervention schedule with a traditional schedule that includes frequent shifts of 24 hours or longer.

**Study Population:**

Second and third year (PGY2 and PGY3) residents

**Study Design:**

Multi-center randomized crossover trial

**Interventions:**

Sleep and circadian science-based intervention schedule versus a traditional schedule

**Primary outcomes:**

Resident-related preventable adverse events and near misses

**Secondary Outcomes:**

ICU-wide preventable adverse events and near misses

Resident neurobehavioral performance and predicted driving safety

**Study Duration:**

12 months (4 month wash-in period followed by 8 months of data collection)

## 1.1 STUDY AIMS

### 1.1.1 Aim 1:

To test the hypothesis that PGY2&3 residents working on an *SCS intervention schedule* will make significantly fewer harmful medical errors (preventable adverse events) and other serious medical errors (near misses) while caring for ICU patients than residents working on a *traditional schedule*; (*primary endpoints: resident-related preventable adverse events and near misses*)

### 1.1.2 Aim 2:

To test the hypothesis that rates of harmful medical errors (preventable adverse events) and other serious medical errors (near misses) *throughout the ICU* (i.e., those involving and those not involving residents) will be lower in ICUs when PGY2&3 residents work on an *SCS intervention schedule* than when residents work on a *traditional schedule*; (*major secondary endpoints: ICU-wide preventable adverse events and near misses*)

### 1.1.3 Aim 3:

To test the hypothesis that resident physicians' risk of neurobehavioral performance failures and motor vehicle crashes – as assessed through simple visual reaction time tasks [Johns Drowsiness Score (JDS) and Psychomotor Vigilance Task (PVT) lapses] – will be lower on the *SCS intervention schedule* than on the *traditional schedule*. (*major secondary endpoints: resident neurobehavioral performance and predicted driving safety*)

## 1.2 BACKGROUND AND RATIONALE

Sleep deficiency and circadian disruption degrade human alertness and performance both in laboratory and occupational settings. Over the past decade, a series of studies have found that first-year residents (interns; PGY1s) working recurrent extended duration shifts ( $\geq 24$  hours) make more serious medical errors than do those working shifts of  $\leq 16$  consecutive hours; moreover, PGY1s working extended duration shifts suffer more injuries on the job, and have an increased risk of motor vehicle crashes (MVCs) on the drive home from work.(1-8) In 2009, after a year-long comprehensive study, the Institute of Medicine (IOM) concluded that while it remained unclear whether resident sleep deprivation led to patient harm, “the scientific evidence base establishes that human performance begins to deteriorate after 16 hours of wakefulness.”(9;10) They consequently called for the elimination of all resident physician shifts without sleep over 16 consecutive hours.

In response, beginning in July 2011, the Accreditation Council for Graduate Medical Education (ACGME) limited interns to no more than 16 consecutive hours of work; second year (PGY2) and higher residents, however, will continue to work for up to 28 consecutive hours.(11) In choosing not to more substantively limit the hours of PGY2 and higher residents

– who represent approximately 80% of all physicians-in-training – the ACGME indicated that in its view, insufficient data existed to support policy change for more senior trainees.

In this study, we seek to conclusively address two knowledge gaps: 1) the lack of data on the relationship between PGY2 and higher sleep deprivation and patient safety; and 2) the lack of data on the relationship between resident sleep deprivation and preventable patient injuries.

### 1.3 STUDY DESIGN AND INTERVENTIONS

The study is a clustered randomized controlled trial to evaluate the effectiveness of eliminating residents' traditional 24-hour shifts in ICUs. The trial will take place in 6 academic medical centers nationwide, in three waves of two centers each. (Figure 1) One of each pair of units will initially be randomly assigned to the traditional schedule (i.e., in which overnight shifts of 24-28 hours continue to occur every 4 nights), or to the SCS intervention schedule (i.e., in which residents are limited to 16 consecutive work hours; sleep before night duty is promoted; and time off is arranged to allow recovery from sleep debt.)

Our planned timeline will be as follows: after a 2 month planning and startup period, during which staff will be recruited and hired, the intervention will be implemented in one randomly selected PICU in study wave 1; the traditional schedule will continue in the other PICU. There will be a 4-month wash-in period, after which time 8 months of data collection will take place in intervention (in black, Figure 1) and traditional (in blue) ICUs. After 8 months of data collection, the units will cross over (traditional to intervention schedule; intervention to traditional). Following another 4-month wash-in period, there will be 8 additional months of data collection. Study sites in waves two and three will follow the same pattern. Of note, each intervention period will be scheduled to occur entirely within a single academic year, and will be preceded or followed (12 months apart) by a control period that will also occur entirely within an academic year.

**Figure 1. Timeline**

## **1.4 SELECTION AND ENROLLMENT OF PARTICIPANTS**

All second and third year residents at the six clinical centers will be invited to enroll in the study. The only exclusion criteria is that the resident is at least 21 years of age. Four to eight residents will be recruited per month at each clinical center for total of approximately 50 residents per site and approximately 300 subjects study-wide.

### **1.4.1 Recruitment**

Sites will submit a waiver of informed consent for the collection of patient data, but will obtain residents' written informed consent to observe them, and collect resident-specific data. Working with program directors at each hospital, the Principal Investigators will make presentations each year to all residents to describe our study and request volunteer participants. Residents are free not to participate in the study; if they choose not to participate, they will not be followed by observers and no other data will be collected from them, but the unit schedule will proceed on the *traditional* or *SCS intervention schedule* as planned.

### **1.4.2 Randomization**

The intervention will be implemented in one randomly assigned study site in each of the three waves and the second site will remain on the traditional schedule. After 8 months of data collection, the units will cross over (traditional to intervention schedule; intervention to traditional). The Data Coordinating Center (DCC) will be responsible for randomly assigning sites to their initial study arm.

### **1.4.3 Preparation of subjects**

Before the start of each study, volunteers will receive a detailed explanation of the procedures involved in the study. They will also attend an educational seminar prior to the implementation of the intervention schedule designed to provide an overview of sleep and circadian science, and to convey the importance of complying with the protocol by attempting to sleep prior to night shifts. They will be asked to complete a baseline survey, which will include the Sleep Disorders and Berlin Sleep Questionnaires.

## **1.5 STUDY PROCEDURES**

The study will take place in pediatric intensive care units (PICUs). In general, subjects will continue to carry out their normal activities and responsibilities when working either the intervention or traditional schedule. Throughout the PICU rotations, subjects will complete a daily sleep diary; will wear actiwatches, described further below, to validate the results of self-reported sleep; and will wear Optalert glasses on the commute to and from work. They will also periodically complete psychomotor vigilance tests (PVTs) to monitor their vigilance. At the completion of their rotations, all subjects will complete an End of Rotation survey. For every experimental intervention, there will be written protocols and checklists used to insure uniformity in the execution of standard procedures.

### **1.5.1 Detection of Errors and Adverse Events**

We will use a very intensive, four-pronged data collection approach to comprehensively measure rates of all errors and adverse events.

#### **1.5.1.1 Continuous Observation**

A team of five physician research associates will conduct direct observation of resident subjects working in the units, 24 hours per day, 7 days per week. The observers will share this responsibility, working in eight-hour shifts. All suspected adverse events and errors will be documented on tablet-based data forms, and transmitted to the research nurse, who will gather follow-up data on them while conducting his or her daily chart reviews, as described below. The observer will also record and classify all medical activities in which the study subject engages, including but not limited to performance of procedures, test and medication ordering, and test interpretation. Suspected adverse events and incidents will be identified and classified. Follow-up of all suspected adverse events and errors detected by the observers will be performed by the nurse data extractors, who will collect additional information.

#### **1.5.1.2 Voluntary and solicited reports**

Forms will be made available and prominently posted in the ICUs to facilitate voluntary reporting of possible errors and events by nurses and other clinical staff. Chart reviewers will also request reports from staff of errors and adverse events 5 days per week. Any reported error or event will be pursued by the nurse data extractors, who will collect additional information.

#### **1.5.1.3 Collection of formal incident reports**

In each hospital, formal incident reports will be collected if permitted; if any institutions will not allow access to these data, we will request that duplicate study reports be filed by clinical staff on our study units when they complete formal reports. In addition, in any hospitals with computerized adverse event detection systems, the computerized AE monitors will also be interrogated for study-unit events. Nurse data extractors will collect additional information on each incident identified.

#### **1.5.1.4 Chart surveillance**

The nurse data extractors will serve as the focal point for data collection and organization, and will follow up and review all data collected by observers, reported by staff, and detected via incident reporting systems. In addition to coordinating collection from other sources, reviewers will examine all orders and charts 5 days per week; a focused version of the Institute for Healthcare Improvement (IHI) Global Trigger Tool (consisting of the intensive care module, cares module, and medication module triggers)(12) will be used to increase the sensitivity of adverse event detection. Reviews on Monday will include a review of the weekend. Data collected for each incident will include a description and classification of the event, patient information, services and personnel involved, and additional work resulting from the event. Medication incidents will further include name, dose, route and category of the drug involved.

### 1.5.2 Classification by severity, attribution, and preventability

Physician observers and research nurses will identify suspected errors and adverse events. Two independent physician reviewers will subsequently classify events as errors, potential adverse events (near misses), or adverse events. All events will be rated on severity using the modified NCC-MERP scale.(12;13) Preventability will be rated using a four point Likert scale. Disagreements will be resolved by discussion. Events for which consensus cannot be reached will be re-rated by a third reviewer. Pre-discussion inter-rater reliability will be evaluated with the Kappa statistic.

### 1.5.3 Identification of patient risk factors

Clinical and demographic data for all patients admitted to study units will be collected by the observers from patient records and institutional administrative databases during lulls in unit activity. Severity of illness will be assessed using a standardized illness severity score, such as PRISM.(14) Morbidity and disability data will be collected until discharge for all patients with an adverse event, as will data about the complexity of conditions, interventions, and drug regimens, including number and types of drugs and interventions.

### 1.5.4 Measuring Sleep and Fatigue

In addition to data on patient safety, we will collect data on residents' sleep and work hours using the methods described below.

#### 1.5.4.1 Sleep and work logs

A diary of sleep and wake times will be maintained by the research volunteers. A post-sleep questionnaire will be completed immediately following wake time from all sleep episodes and will provide information on subjective evaluation of sleep onset, duration, consolidation, quality, and wakefulness during sleep, as well as daily work hours. Our sleep and work logs have previously been validated; hours of sleep and work reported using this methodology have a high correlation with polysomnographically-validated total sleep time ( $r=0.94$ ) as well as 3<sup>rd</sup>-party documented work hours ( $r=0.98$ ).<sup>(2)</sup>

#### 1.5.4.2 Ambulatory physiologic monitoring

To further validate reported sleep times in this study, wrist activity and ambient light levels will be monitored for the entire duration of residents' rotations with a solid-state, portable data collection device (Motionlogger BASIC; Ambulatory Monitoring, Inc., Ardsley, NY). The Motionlogger recorder is a small wrist worn device that measures activity and ambient light exposure; it is waterproof and powered by a 3V, 150 mAmp-hr Lithium Manganese battery that has a lifetime of 60 days. Data are preserved if the battery expires.

### 1.5.5 Measuring Resident Vigilance and Driving Safety

#### 1.5.5.1 Optalert

**Figure 2. Optalert glasses**

Optalert is an innovative technology that uses infrared oculography to monitor the alertness of an individual continuously. The Optalert glasses contain a small light emitting diode (LED) positioned below and in front of the eye, attached to a frame designed to hold clear or prescription lenses. **(Figure 2)** Brief pulses of invisible infrared (IR) light (each lasting

70  $\mu$ s, wavelength 935 nm) are directed up in a 30 degree cone of light centered on the lower edge of the upper eyelid and repeated at a frequency of 500 Hz. The total IR light reflected back from the eye and eyelid is detected by a phototransistor in the frame beside the LED.

A microprocessor, housed in the arm of the glasses, controls the timing and other characteristics of the IR pulses, and digitizes the analogue output from the sensors. The power supply and the serial output from the glasses via a light cable connected to a personal digital assistant (PDA). This PDA provides a variety of different analyses of the recorded signals including reflecting position and the velocity of movements. The velocity of movements are calculated 500 times per second as the change in position (uncalibrated units) per 50 ms. The durations of the separate components of blinks and of other eye and eyelid movements, and their AVRs, are measured by software that included period-amplitude analysis of both the position and velocity signals and classification of all periods and amplitudes per minute.

These analyses automatically generate an alertness score (Johns Drowsiness Scale, JDS), a composite measure of alertness based on many variables characterizing blinks, including the ratio of the amplitude to the maximum velocity (AVR) of eyelid movements for closing and reopening of the eyelids, as well as the duration of eyelids closing, of remaining closed, and of reopening during blinks. The weighting for each variable in the JDS was derived from multiple regression analysis, comparing results of Optalert recordings before and after sleep deprivation. The JDS is calculated each minute on a 0-10 scale. Normal values are 0-4, and do not require adjustment for individual subjects.

#### 1.5.5.2 PVT.

In the proposed study, we will also have resident physician subjects complete Psychomotor Vigilance Testing – an established metric of vigilance that is sensitive to sleep deprivation and circadian misalignment (15) – during one shift per week, every five hours. Completing the PVT requires 10 minutes and provides data on vigilance that will be used to derive an independent measure of neurobehavioral performance while subjects are on the job.

### 1.5.6 Additional Measures

#### 1.5.6.1 Self-reported attentional failures, motor vehicle crashes (MVCs), and percutaneous injuries

Through end-of-rotation surveys, we will also collect data on residents' self-reported attentional failures, MVCs, near-miss MVCs, and percutaneous injuries using the instruments we previously developed for use in our national cohort study. Any reported MVCs and percutaneous injuries will be validated by the collection of objective data (e.g. police reports, repair bills, etc. for MVCs), as was done in our cohort study.(1;4) When MVCs occur on the commute to and from work, we will also have detailed Optalert data available. We believe that collecting MVC and percutaneous data is important given their implications for resident safety, but with 300 anticipated subjects in the study, and the relative infrequency of these occupational injuries,(1;4) we will have power to detect an effect of the intervention on these outcomes only if they are reduced more than two-fold. As such, analysis of these outcomes will be considered exploratory.

#### 1.5.6.2 Educational Measures

We will also, through the daily diaries and the end-of-rotation survey, collect preliminary data on residents' educational experiences. Residents will provide daily estimates on their logs of the amount of time spent in didactic education and the amount of time spent reading for knowledge acquisition. On their end-of-rotation surveys, they will report their impressions of their educational experience.

#### 1.5.6.3 Collection of Salivary Samples for Subsequent Genetic Analyses

In light of the emerging science exploring the genetic predictors of susceptibility to sleep loss and circadian misalignment, salivary samples will be collected to measure genetic modifiers of the *SCS intervention's* effects. Unfortunately, the limited number of subjects (~300) being studied in this proposed trial precludes conducting genome-wide association studies to determine what genes may convey an increased risk of fatigue-related error, and as yet, no candidate gene has been independently verified to convey altered vulnerability to the performance-impairment associated with sleep deprivation. However, given that this study will gather unprecedented data on sleep, performance, and safety, and the likelihood that one or more candidate genes will be verified in the near future, we will collect samples and analyze the DNA of all participants who agree to participate in a future genetic evaluation. These specimens will then be available at a later time to evaluate whether candidate genes verified to affect vulnerability to sleep loss predict the probability of Optalert lapses or of making an error that leads to an AE.

### 1.6 SAFETY ASSESSMENTS

The study will be looking for the occurrence of adverse events that occur in ICU care; some are preventable, and some are not. Data on adverse events will be systematically collected and reviewed by the DSMB after each 8 month data collection period. Rates of adverse events will be compared and the DSMB will subsequently make periodic recommendations on whether to continue, modify, or terminate the study. From prior studies, we have found that the cause of detected adverse events in hospitals cannot in most cases be reliably assigned on a case by case basis (e.g., was acquisition of a catheter-related bloodstream infection due to a resident's work schedule? A nurse error? Another cause?), so we anticipate that there will not be discrete, individual adverse events that would modify an assessment of the safety of the intervention or traditional work schedule's risks; rather, we expect that through epidemiologic methods, we will obtain useful data on the safety of the intervention vs. traditional work schedules, and act as needed. However, if there are discrete events that clinical staff or study investigators believe are attributable to either the intervention or traditional work schedule, these events will be brought to the attention of the DSMB for review and action as needed.

### 1.7 STATISTICAL CONSIDERATIONS

#### 1.7.1 Outcomes and Statistical Analyses

We will compare resident-related (Specific Aim 1) and total (Specific Aim 2) rates of harmful medical errors (preventable adverse events) on the two schedules. As a secondary measure, rates of non-harmful serious medical errors (i.e., near misses) will also be compared. In an intention-to-treat analysis, rates will be compared by schedule using Poisson models with

compound symmetric working correlation and robust standard errors to account for both over-dispersion and clustering by clinical center (16), and the number of patient-days at risk in each center and period included as so-called offset. The models will control for period effects and will be used to assess treatment-period interaction, a standard check with crossover trials(17).

In addition, actigraphy and sleep diaries will be used to ascertain the minimum and mean number of hours of sleep obtained per night, total sleep time, wake after sleep onset (WASO; minutes), and sleep efficiency. We will also compare performance on the Johns Drowsiness Score (JDS), based on results captured by Optalert, and the Psychomotor Vigilance Test (PVT). Specifically, we will compare the time-weighted average JDS score for each shift; the proportion of the shift minutes spent with a JDS score above 4.5, the cutoff for impairment; and the numbers of lapses in vigilance, defined as a reaction time >500 ms, on the PVT. These Intention-to-treat comparisons by will be made using linear mixed models for repeated measures, with nested random effects to account for clustering within clinical center and residents<sup>12</sup>. Outcomes will be normalized as necessary; generalized linear mixed models appropriate for other outcome distributions, and/or bootstrap standard errors will be used if adequate normalization cannot be achieved. In preliminary analyses, we will assess the comparability of the residents in the intervention and control periods in terms of age, gender, post-graduate year (PGY2 vs PGY3), as well as other potential confounders of the intervention. If imbalances are found, we will conduct sensitivity analyses in which we flexibly adjust for the potential confounders.

### 1.7.2 Sample Size and Minimum Detectable Effects

Based on the Intern Sleep and Patient Safety Study, during which 2,203 patient-days were accrued under both schedules over a total of 8.5 months at a single center with 2 ICUs totaling

Serious medical errors	Resident-related rate per 1000 patient-days	MD-RRR with Scale Factor of 1.0 (2.0)	Unit rate per 1000 patient-days	MD-RRR with Scale Factor of 1.0 (2.0)
overall	136.0	8.0% (11.2%)	193.2	6.7% (9.4%)
intercepted	70.3	11.0% (15.5%)	95.1	9.5% (13.3%)
non-intercepted	44.8	13.8% (19.2%)	59.5	11.9% (16.7%)
<b>Preventable AEs</b>	<b>20.9</b>	<b>19.8% (27.5%)</b>	<b>38.6</b>	<b>14.8% (20.6%)</b>

**Figure 3, power table.** Minimum detectable relative rate reductions (MD-RRRs) detectable with 90 percent power in two-sided tests (with alpha of 5%) for serious medical errors, by sub-type of error, using Poisson models. The primary outcomes of interest, resident-related and total preventable AEs, are bolded.

20 beds, we estimate that approximately 46,080 patient-days will be accrued across the six centers in this study, each contributing an observation period of 8 months on each

schedule, with an average census of 16 patients, or 80% of an average 20 beds. Assuming that the baseline error rates per-patient day on the standard schedule are the same as those observed in the Intern Sleep and Patient Safety Study, the new sample will provide 90% power to detect relative rate reductions (MD-RRRs) on the sleep and circadian science-based (SCS) intervention schedule as shown in Figure 3. Estimates are shown first assuming a scale factor of 1.0, corresponding to a Poisson distribution, while conservative estimates assuming an over-dispersed Poisson distribution with a scale factor of 2.0, are shown in parentheses. For overall serious medical errors, we will have 90% power to detect reductions in both

resident-related and unit error rates of 7-11%; MD-RRRs for intercepted and non-intercepted medical errors will be between 9.5 and 19%. Even for the least frequent outcome but that of greatest interest, resident-related preventable AEs, we will have 90% power to detect a relative reduction of 19.8% if the distribution is Poisson, and 27.5% under our conservative assumptions about over-dispersion. The actual reductions seen in our preliminary study were larger than these thresholds in each sub-category of resident-related serious errors, including resident-related preventable adverse events. Thus, we expect to be adequately powered to draw definitive conclusions regarding the effectiveness of the *SCS schedule* intervention. In assessing interaction/period interactions, MD-RRRs will be fourfold larger than the main intervention effects. However, because residents will participate in at most one period, the potential for carryover effects is much smaller than in most crossover studies.

In addition, for sleep and work hours as well as JDS and PVT results, we estimate the expected sample of 300 residents will provide 90% power in 2-sided tests with alpha of 5% to detect standardized between-group differences of 0.30 to 0.37 standard deviations of the outcome,

Outcome	MDE
Sleep hours (weekly)	1.75 / 1.92 / 2.21
Work hours (weekly)	1.39 / 1.53 / 1.76
Standardized units	0.30 / 0.32 / 0.37
<b>Figure 4, minimum effects on resident outcomes</b> detectable with 90% power in two-sided 5% tests, with design effects of 1.25/1.5/2.0.	

depending on the design effect due to clustering within centers and residents; calculations are shown in Figure 4 for minimum detectable effects (MDEs) for sleep and work hours, based on standard deviations observed for sleep and work hours observed in the ICU pilot study conducted at Brigham and Women's Hospital. Because this pilot study did not collect data on other sleep outcomes (e.g. WASO, sleep efficiency) or the

performance outcomes (JDS and PVT), the standardized units are also shown in Figure 4. These calculations show that the study will be powered to detect small-to-moderate intervention effects on these outcomes, even if the design effect is as large as 2.

## 1.8 DATA COLLECTION AND QUALITY ASSURANCE

### 1.8.1 Data Acquisition and Transmission

The DCC will develop a front-end component for data entry and transmission. Data would be entered at remote sites on secure mobile computing devices and transmitted a minimum of once a day via secure transfer. Data received will be automatically imported into SQL tables and integrated into our standard data system. Data will be available for review/updating via the standard study website within 24-48 business hours. The DCC will create and maintain a comprehensive programmer's guide for all the data systems it provides.

### 1.8.2 Data Collection and Editing

Capturing data electronically will reduce the risk of missing data. Furthermore, edits checks may be built into the instruments to flag out of range or inconsistent data. Further custom edit checks will be written and run on data received at the DCC. Each hour, the cumulative study data is subjected to these custom edits to ensure completeness, consistency and validity of the data. The results of the error-checking procedures are posted to the study website, which the study staff will check daily to both confirm that the DCC has successfully received all of the transmitted forms and to address errors that have been detected by the edit system. The Project Manager and other Clinical Coordinating Center (CCC) staff will be responsible for

checking the daily data edits and working in conjunction with the sites to address them. This data entry/data editing process is monitored by a number of standard monitoring reports that will be available on the website. An audit trail is maintained which includes the date of change, time of change, description of data change, and the study ID of the person making the change.

The DCC will also serve as the Reading Center for the actigraphy, Optalert and PVT datasets. DCC staff will perform an initial review of the files upon receipt and report any issues to the clinical site staff; later DCC staff will clean and merge the device data with the form data.

The DCC will prepare comprehensive ‘clean’ datasets for analysis, providing the analysis-ready files to the CCC and others as necessary, for statistical analysis purposes. The DCC will also ensure that any entity receiving the dataset will have a Data Use Agreement on file, signed by the appropriate institutional authority. The DCC will also be responsible for preparing a public release dataset to be housed within NHLBI’s BioLINCC (or a comparable public data repository) no later than 3 years after the end of the trial or 2 years after the main paper has been published, whichever comes first.

### **1.8.3 Data Management and Study Progress**

The study website which includes a number of data management features and reports to enable clinical sites and study investigators to monitor data collection and study progress. Data Management features include a data inventory, lists of missing forms and queries by participant ID, and tools to resolve queries and update data via the website. Reports can be custom-designed to meet study needs and could include:

- Enrollment in aggregate and by site
- Demographics in aggregate and by site
- Early Discontinuation in aggregate and by site

### **1.8.4 Staff Training**

Site staff (physician observers, nurse data extractors and study coordinators) will be trained intensively in the detection of medical errors and adverse events using an established training protocol. Inter-rater reliability will be verified during the study. Staff will also be instructed on procedures for entering data into electronic data collection forms and transmitting these data to the DCC. Lastly, staff will be trained in the operation of the actigraph and Optalert devices, as well as the PVT tests.

## **1.9 PARTICIPANT RIGHTS AND CONFIDENTIALITY**

### **1.9.1 Institutional Review Board (IRB) Review**

This protocol and informed consent documents, and any subsequent modifications, will be reviewed and approved by the IRB or ethics committee responsible for oversight of each of the clinical sites, as well as the clinical and data coordinating centers.

### **1.9.2 Informed Consent Forms**

Informed Consent documents will be maintained at individual sites and coordinators must ensure that they are using an up-to-date, IRB approved version of the consent form. A signed

Informed Consent form will be obtained from each participant. The Informed Consent will describe the purpose of the study, the procedures to be followed, and the risks and benefits of participation and must comply with the requirements of the study site's Institutional Review Board. A copy of the Informed Consent will be given to each participant and provision of the copy will be documented in the study participant's record. The DCC will ensure that all clinical site informed consents are consistent and include required elements.

### **1.9.3 Participant Confidentiality**

#### **1.9.3.1 Clinical Sites**

In order to protect confidentiality of the research participants as well as the patients they treat, both will be assigned a unique study identification number, which will be used to refer to them on all study forms. The list of codes linking resident-subjects' and patients' names and study IDs will be kept by each site PI on a separate password protected computer in a locked office at that site. Each site PI will be responsible for ensuring the security of these data. These identifying data will not be transmitted outside of the originating institution. Risk to patient confidentiality will likewise be minimized. All information will be de-identified at the point of data analysis.

#### **1.9.3.2 Data Coordinating Center**

The DCC follows standard operating procedures (SOPs) for computer system security to ensure the confidentiality and validity of study data. The SOPs are designed to prevent unauthorized access and limit authorized access to our computer systems and are in compliance with established standards for Information Technology Security. Our network is privately maintained, hardware fire-walled and none of the workstations or database servers can be directly addressed from outside the Local Area Network. Study website and database access requires a network domain account with appropriate account-specific permission on the database. All requests for new accounts and access to the database must be documented by a System Access Request Form signed by the project director.

## **1.10 COMMITTEES**

### **1.10.1 Steering Committee**

The Steering Committee will be responsible for all decisions concerning the scientific and technical conduct of the study. It will appoint the analysis and publications committee and writing groups, ensuring that information from the study is disseminated in the scientific literature and at scientific meetings. The committee will be chaired by Dr. Czeisler and will include the lead site investigator from the clinical and data coordinating center and each of the clinical sites. The Steering Committee will have one in-person meeting on an annual basis, and will meet by teleconference on at least a bi-monthly basis. The Steering Committee consists of the following members:

Charles A. Czeisler, PhD, MD	Chair, PI, CCC, Brigham and Women's Hospital
Christopher P. Landrigan, MD, MPH	PI, CCC, Brigham and Women's Hospital
Katie L. Stone, PhD	PI, DCC, California Pacific Medical Center
Susan Redline, MD, MPH	Chair, Sleep Research Network

Ken Wright, PhD	PI, University of Colorado
Gwen Erkonen, MD	PI, University of Iowa
Pearl Yu, MD	PI, University of Virginia
Phyllis Zee, MD, PhD	PI, Northwestern University
Sue Poynter, MD	PI, University of Cincinnati
Michael Twery, PhD	Project Scientist, NHLBI

### 1.10.2 Executive Committee

An Executive Subgroup of the Steering Committee will be responsible for decisions that require attention between Steering Committee Meetings and for major financial, administrative and operational decisions. The Executive Committee will meet via teleconference at least monthly and will consist of the following members:

Charles A. Czeisler, PhD, MD	PI, CCC, Brigham and Women's Hospital
Christopher P. Landrigan, MD, MPH	PI, CCC, Brigham and Women's Hospital
Katie L. Stone, PhD	PI, DCC, California Pacific Medical Center
Michael Twery, PhD	Project Scientist, NHLBI

### 1.10.3 Principal Planning Group

A planning group comprised of the Principal Investigators and project staff of both the CCC and DCC will be responsible for the development of study documents, including the forms, protocol and operations manual, as well as the day-to-day management of the trial. The Principal Planning Group will meet via teleconference at least monthly and will consist of the following members:

Charles A. Czeisler, PhD, MD	PI, CCC, Brigham and Women's Hospital
Christopher P. Landrigan, MD, MPH	PI, CCC, Brigham and Women's Hospital
Joshua Stephens	CCC, Brigham and Women's Hospital
Katie L. Stone, PhD	PI, DCC, California Pacific Medical Center
Dana R. Kriesel, MPH	PD, DCC, California Pacific Medical Center

### 1.10.4 Working Groups

Members of the Steering Committee will form working groups to manage and oversee specific aspects of the trial. These include: (1) Data Management and Data Quality; (2) Patient Safety and PICU Quality Outcomes; (3) Sleep, Performance and Health Outcomes; and (4) Education Outcomes. Working groups will meet on an as needed basis.

### 1.10.5 Data and Safety Monitoring Board

To monitor the study for the possibility that the intervention schedule has an adverse effect on safety, a multidisciplinary Data and Safety Monitoring Board (DSMB) comprised of financially disinterested members will be appointed by NHLBI, with guidance from DCC. The DSMB will monitor the quality and integrity of the data emerging from the proposed study; assess the adequacy of recruitment, compliance, follow-up and other aspects of study execution; and review interim analyses of the major outcomes of the trial to identify safety issues and make periodic recommendations on whether to continue, modify, or terminate the study. The DSMB will be an advisory board to NHLBI and the Steering Committee. The DSMB will work under a Charter that will be developed by the DCC, working in tandem with

NHLBI. The DCC will support the DSMB by preparing interim reports for review at DSMB meetings; and by organizing scheduled and ad hoc meetings of the DSMB as needed. Please see the DSMB Charter for more details.

### **1.11 CONFLICT OF INTEREST**

The DCC will be responsible for surveying the key personnel at each study site on an annual basis regarding any conflicts of interest that may have arisen. The Executive Committee will review the results of these annual surveys and determine if any action is necessary.

**PROTOCOL SUMMARY****Objective:**

To conduct a multi-center randomized crossover trial in six pediatric ICUs staffed by PGY2 and PGY3 residents to compare the effectiveness and safety of a sleep and circadian science-based (SCS) intervention schedule with a traditional schedule that includes frequent shifts of 24 hours or longer.

**Study Population:**

Second and third year (PGY2 and PGY3) residents

**Study Design:**

Multi-center randomized crossover trial

**Interventions:**

Sleep and circadian science-based intervention schedule versus a traditional schedule

**Primary outcomes:**

Resident-related preventable adverse events and near misses

**Secondary Outcomes:**

ICU-wide preventable adverse events and near misses

Resident neurobehavioral performance and predicted driving safety

**Study Duration:**

12 months (4 month wash-in period followed by 8 months of data collection)

## 1.1 STUDY AIMS

### 1.1.1 Aim 1:

To test the hypothesis that PGY2&3 residents working on an *SCS intervention schedule* will make significantly fewer harmful medical errors (preventable adverse events) and other serious medical errors (near misses) while caring for ICU patients than residents working on a *traditional schedule*; (*primary endpoints: resident-related preventable adverse events and near misses*)

### 1.1.2 Aim 2:

To test the hypothesis that rates of harmful medical errors (preventable adverse events) and other serious medical errors (near misses) *throughout the ICU* (i.e., those involving and those not involving residents) will be lower in ICUs when PGY2&3 residents work on an *SCS intervention schedule* than when residents work on a *traditional schedule*; (*major secondary endpoints: ICU-wide preventable adverse events and near misses*)

### 1.1.3 Aim 3:

To test the hypothesis that resident physicians' risk of neurobehavioral performance failures and motor vehicle crashes – as assessed through drive diaries, End of Rotation Survey and simple visual reaction time tasks [Psychomotor Vigilance Task (PVT) lapses] – will be lower on the *SCS intervention schedule* than on the *traditional schedule*. (*major secondary endpoints: resident neurobehavioral performance and predicted driving safety*)

## 1.2 BACKGROUND AND RATIONALE

Sleep deficiency and circadian disruption degrade human alertness and performance both in laboratory and occupational settings. Over the past decade, a series of studies have found that first-year residents (interns; PGY1s) working recurrent extended duration shifts ( $\geq 24$  hours) make more serious medical errors than do those working shifts of  $\leq 16$  consecutive hours; moreover, PGY1s working extended duration shifts suffer more injuries on the job, and have an increased risk of motor vehicle crashes (MVCs) on the drive home from work.(1-8) In 2009, after a year-long comprehensive study, the Institute of Medicine (IOM) concluded that while it remained unclear whether resident sleep deprivation led to patient harm, “the scientific evidence base establishes that human performance begins to deteriorate after 16 hours of wakefulness.”(9;10) They consequently called for the elimination of all resident physician shifts without sleep over 16 consecutive hours.

In response, beginning in July 2011, the Accreditation Council for Graduate Medical Education (ACGME) limited interns to no more than 16 consecutive hours of work; second year (PGY2) and higher residents, however, will continue to work for up to 28 consecutive hours.(11) In choosing not to more substantively limit the hours of PGY2 and higher residents – who represent approximately 80% of all physicians-in-training – the ACGME indicated that in its view, insufficient data existed to support policy change for more senior trainees.

In this study, we seek to conclusively address two knowledge gaps: 1) the lack of data on the relationship between PGY2 and higher sleep deprivation and patient safety; and 2) the lack of data on the relationship between resident sleep deprivation and preventable patient injuries.

### 1.3 STUDY DESIGN AND INTERVENTIONS

The study is a clustered randomized controlled trial to evaluate the effectiveness of eliminating residents' traditional 24-hour shifts in ICUs. The trial will take place in 6 academic medical centers nationwide, in three waves of two centers each. (Figure 1) One of each pair of units will initially be randomly assigned to the traditional schedule (i.e., in which overnight shifts of 24-28 hours continue to occur every 4 nights), or to the SCS intervention schedule (i.e., in which residents are limited to 16 consecutive work hours; sleep before night duty is promoted; and time off is arranged to allow recovery from sleep debt.)

Our planned timeline will be as follows: after a 2 month planning and startup period, during which staff will be recruited and hired, the intervention will be implemented in one randomly selected PICU in study wave 1; the traditional schedule will continue in the other PICU. There will be a 4-month wash-in period, after which time 8 months of data collection will take place in intervention (in black, Figure 1) and traditional (in blue) ICUs. After 8 months of data collection, the units will cross over (traditional to intervention schedule; intervention to traditional). Following another 4-month wash-in period, there will be 8 additional months of data collection. Study sites in waves two and three will follow the same pattern. Of note, each intervention period will be scheduled to occur entirely within a single academic year, and will be preceded or followed (12 months apart) by a control period that will also occur entirely within an academic year.

**Figure 1. Timeline**

### 1.4 SELECTION AND ENROLLMENT OF PARTICIPANTS

All second and third year residents at the six clinical centers will be invited to enroll in the study. The only exclusion criteria is that the resident is at least 21 years of age. Four to eight residents will be recruited per month at each clinical center for total of approximately 50 residents per site and approximately 300 subjects study-wide.

#### **1.4.1 Recruitment**

Sites will submit a waiver of informed consent for the collection of patient data, but will obtain residents' written informed consent to observe them, and collect resident-specific data. Working with program directors at each hospital, the Principal Investigators will make presentations each year to all residents to describe our study and request volunteer participants. Residents are free not to participate in the study; if they choose not to participate, they will not be followed by observers and no other data will be collected from them, but the unit schedule will proceed on the *traditional* or *SCS intervention schedule* as planned.

#### **1.4.2 Randomization**

The intervention will be implemented in one randomly assigned study site in each of the three waves and the second site will remain on the traditional schedule. After 8 months of data collection, the units will cross over (traditional to intervention schedule; intervention to traditional). The Data Coordinating Center (DCC) will be responsible for randomly assigning sites to their initial study arm.

#### **1.4.3 Preparation of subjects**

Before the start of each study, volunteers will receive a detailed explanation of the procedures involved in the study. They will also attend an educational seminar prior to the implementation of the intervention schedule designed to provide an overview of sleep and circadian science, and to convey the importance of complying with the protocol by attempting to sleep prior to night shifts. They will be asked to complete a baseline survey, which will include the Sleep Disorders and Berlin Sleep Questionnaires.

### **1.5 STUDY PROCEDURES**

The study will take place in pediatric intensive care units (PICUs). In general, subjects will continue to carry out their normal activities and responsibilities when working either the intervention or traditional schedule. Throughout the PICU rotations, subjects will complete a daily sleep diary and wear actiwatches, described further below, to validate the results of self-reported sleep. They will also periodically complete psychomotor vigilance tests (PVTs) to monitor their vigilance. At the completion of their rotations, all subjects will complete an End of Rotation survey. For every experimental intervention, there will be written protocols and checklists used to insure uniformity in the execution of standard procedures.

#### **1.5.1 Detection of Errors and Adverse Events**

We will use a very intensive, four-pronged data collection approach to comprehensively measure rates of all errors and adverse events.

#### 1.5.1.1 Continuous Observation

A team of five physician research associates will conduct direct observation of resident subjects working in the units, 24 hours per day, 7 days per week. The observers will share this responsibility, working in eight-hour shifts. All suspected adverse events and errors will be documented on tablet-based data forms, and transmitted to the research nurse, who will gather follow-up data on them while conducting his or her daily chart reviews, as described below. The observer will also record and classify all medical activities in which the study subject engages, including but not limited to performance of procedures, test and medication ordering, and test interpretation. Suspected adverse events and incidents will be identified and classified. Follow-up of all suspected adverse events and errors detected by the observers will be performed by the nurse data extractors, who will collect additional information.

#### 1.5.1.2 Voluntary and solicited reports

Forms will be made available and prominently posted in the ICUs to facilitate voluntary reporting of possible errors and events by nurses and other clinical staff. Chart reviewers will also request reports from staff of errors and adverse events 5 days per week. Any reported error or event will be pursued by the nurse data extractors, who will collect additional information.

#### 1.5.1.3 Collection of formal incident reports

In each hospital, formal incident reports will be collected if permitted; if any institutions will not allow access to these data, we will request that duplicate study reports be filed by clinical staff on our study units when they complete formal reports. In addition, in any hospitals with computerized adverse event detection systems, the computerized AE monitors will also be interrogated for study-unit events. Nurse data extractors will collect additional information on each incident identified.

#### 1.5.1.4 Chart surveillance

The nurse data extractors will serve as the focal point for data collection and organization, and will follow up and review all data collected by observers, reported by staff, and detected via incident reporting systems. In addition to coordinating collection from other sources, reviewers will examine all orders and charts 5 days per week; a focused version of the Institute for Healthcare Improvement (IHI) Global Trigger Tool (consisting of the intensive care module, cares module, and medication module triggers)(12) will be used to increase the sensitivity of adverse event detection. Reviews on Monday will include a review of the weekend. Data collected for each incident will include a description and classification of the event, patient information, services and personnel involved, and additional work resulting from the event. Medication incidents will further include name, dose, route and category of the drug involved.

### 1.5.2 Classification by severity, attribution, and preventability

Physician observers and research nurses will identify suspected errors and adverse events. Two independent physician reviewers will subsequently classify events as errors, potential adverse events (near misses), or adverse events. All events will be rated on severity using the modified NCC-MERP scale.(12;13) Preventability will be rated using a four point Likert scale. Disagreements will be resolved by discussion. Events for which consensus cannot be reached

will be re-rated by a third reviewer. Pre-discussion inter-rater reliability will be evaluated with the Kappa statistic.

### **1.5.3 Identification of patient risk factors**

Clinical and demographic data for all patients admitted to study units will be collected by the research nurses from patient records and institutional administrative databases during lulls in unit activity. Severity of illness will be assessed using ICD-9 codes.

### **1.5.4 Measuring Sleep and Fatigue**

In addition to data on patient safety, we will collect data on residents' sleep and work hours using the methods described below.

#### **1.5.4.1 Sleep and work logs**

A diary of sleep and wake times will be maintained by the research volunteers. A post-sleep questionnaire will be completed immediately following wake time from all sleep episodes and will provide information on subjective evaluation of sleep onset, duration, consolidation, quality, and wakefulness during sleep, as well as daily work hours. Our sleep and work logs have previously been validated; hours of sleep and work reported using this methodology have a high correlation with polysomnographically-validated total sleep time ( $r=0.94$ ) as well as 3<sup>rd</sup>-party documented work hours ( $r=0.98$ ).<sup>(2)</sup>

#### **1.5.4.2 Ambulatory physiologic monitoring**

To further validate reported sleep times in this study, wrist activity and ambient light levels will be monitored for the entire duration of residents' rotations with a solid-state, portable data collection device (Motionlogger BASIC; Ambulatory Monitoring, Inc., Ardsley, NY). The Motionlogger recorder is a small wrist worn device that measures activity and ambient light exposure; it is waterproof and powered by a 3V, 150 mAmp-hr Lithium Manganese battery that has a lifetime of 60 days. Data are preserved if the battery expires.

### **1.5.5 Measuring Resident Vigilance**

#### **1.5.5.1 PVT.**

In the proposed study, we will also have resident physician subjects complete Psychomotor Vigilance Testing – an established metric of vigilance that is sensitive to sleep deprivation and circadian misalignment (14) – during one shift per week, every five hours. Completing the PVT requires 10 minutes and provides data on vigilance that will be used to derive an independent measure of neurobehavioral performance while subjects are on the job. Subjects will also be asked to complete the Karolinska Sleepiness Scale (KSS), a self-report scale that measures alertness, before and after each test.

### **1.5.6 Additional Measures**

#### **1.5.6.1 Self-reported attentional failures, motor vehicle crashes (MVCs), and percutaneous injuries**

Through end-of-rotation surveys, we will also collect data on residents' self-reported attentional failures, MVCs, near-miss MVCs, and percutaneous injuries using the instruments we

previously developed for use in our national cohort study. Any reported MVCs and percutaneous injuries will be validated by the collection of objective data (e.g. police reports, repair bills, etc. for MVCs), as was done in our cohort study.(1;4) When MVCs occur on the commute to and from work, we will also have drive diary data available. We believe that collecting MVC and percutaneous data is important given their implications for resident safety, but with 300 anticipated subjects in the study, and the relative infrequency of these occupational injuries,(1;4) we will have power to detect an effect of the intervention on these outcomes only if they are reduced more than two-fold. As such, analysis of these outcomes will be considered exploratory.

#### 1.5.6.2 Educational Measures

As part of the study, participants will have the option of enrolling in an online educational platform entitled OPENPediatrics. OPENPediatrics is a free, open access, peer-reviewed, digital learning platform that utilizes the latest in innovative technology to provide robust continuing medical education. OPENPediatrics is sponsored through Boston Children's Hospital and IBM and located at Boston Children's Hospital (Website: <http://openpediatrics.org>). Through a feature entitled the Learning Pathways, participants will have access to the ROSTERS curriculum, or a similar ICU learning curriculum approved by each participant's hospital. This curriculum is comprised of 18 lessons by educational experts. Each lesson begins with a pre-test followed by a didactic or procedural demonstration video and concludes with a post-test. This unique format will allow for asynchronous learning, so that participants can complete their educational lessons outside the hospital and apply their knowledge during on-duty hours. OPENPediatrics' robust analytics will allow research staff to track each participant's submissions as they progress through the curriculum. Pre-test and post-test scores as well as duration in each module will allow researchers to note the educational gains made throughout the curriculum, and compare each participant's results in the control and Sleep and Circadian Science-based (SCS) intervention arms. A vigorous set of security measures will allow the analytic data from the application to be securely passed from the application to the data collection program, Cognos. As standard practice for the OPENPediatrics data storage procedures this data will be stored on IBM's secure servers, and IBM's analytic department will control access to this data. All residents in the unit will have access to the platform so no delineation between non subject residents and subject residents can be made by anyone except each site coordinator who will maintain the only identified list of subjects for the site. Resident data specific to each site will be sent from OPENPediatrics to each site coordinator; the site coordinator will then delete all data associated with non-subject residents. These measures are being taken so only site coordinators have knowledge of which data sets are associated with resident subjects. The team will work with the site PI to de-identify the data by removing the user's name/email. The data will only be stored on password-protected computers. Data will only be reported as de-identified, aggregated data. On their end-of-rotation surveys, they will report their impressions of their educational experience.

#### 1.5.6.3 Collection of Salivary Samples for Subsequent Genetic Analyses

In light of the emerging science exploring the genetic predictors of susceptibility to sleep loss and circadian misalignment, salivary samples will be collected to measure genetic modifiers of the *SCS intervention's* effects. Unfortunately, the limited number of subjects (~300) being

studied in this proposed trial precludes conducting genome-wide association studies to determine what genes may convey an increased risk of fatigue-related error, and as yet, no candidate gene has been independently verified to convey altered vulnerability to the performance-impairment associated with sleep deprivation. However, given that this study will gather unprecedented data on sleep, performance, and safety, and the likelihood that one or more candidate genes will be verified in the near future, we will collect samples and analyze the DNA of all participants who agree to participate in a future genetic evaluation. These specimens will then be available at a later time to evaluate whether candidate genes verified to affect vulnerability to sleep loss or of making an error that leads to an AE.

## **1.6 SAFETY ASSESSMENTS**

### **1.6.1 Patient Safety**

The study will be looking for the occurrence of adverse events that occur in ICU care; some are preventable, and some are not. Data on adverse events will be systematically collected and reviewed by the DSMB after each 8 month data collection period. Rates of adverse events will be compared and the DSMB will subsequently make periodic recommendations on whether to continue, modify, or terminate the study. From prior studies, we have found that the cause of detected adverse events in hospitals cannot in most cases be reliably assigned on a case by case basis (e.g., was acquisition of a catheter-related bloodstream infection due to a resident's work schedule? A nurse error? Another cause?), so we anticipate that there will not be discrete, individual adverse events that would modify an assessment of the safety of the intervention or traditional work schedule's risks; rather, we expect that through epidemiologic methods, we will obtain useful data on the safety of the intervention vs. traditional work schedules, and act as needed. However, if there are discrete events that clinical staff or study investigators believe are attributable to either the intervention or traditional work schedule, these events will be brought to the attention of the DSMB for review and action as needed.

### **1.6.2 Resident Safety**

As part of this study, we will ask resident subjects questions about depression, including questions about suicidal thoughts and plans, motor vehicle incidents, drowsy driving, including falling asleep at the wheel, and occupational exposures. The Data Coordinating Center for the study reviews survey responses, and if responses indicate suicidality, 3 or more occupational exposure reports, and/or motor vehicle crashes in which the damage was >\$1000 and/or drowsiness was reported as a factor, the study principle investigator will be asked to follow up with the resident subject. Near misses will not be followed up on. Additionally, initial reports of falling asleep at the wheel will trigger a follow up with by each site's research study coordinator; 3 or more responses of falling asleep while driving will trigger a follow up by each site's principle investigator. Specifically in regards to questions concerning suicide, if resident subjects respond to the question "Over the past two weeks, how often have you thought about or wanted to commit suicide?" with "Some of the time," "Most of the time," or "All of the time," regardless of whether they respond "Yes" or "No" to "Do you have a plan?", the following message will appear on the form: "Your response to the previous questions causes us to be concerned for your welfare. All reports of suicide ideation will be reported to your site PI, who will then initiate your institution's protocols for timely intervention and action, in compliance with their organizational rules and standards." These criteria were discussed and

decided on by the Clinical Coordinating Center, Steering Committee, and voted on and approved by the Data Safety Monitoring Board for this protocol.

## 1.7 STATISTICAL CONSIDERATIONS

### 1.7.1 Outcomes and Statistical Analyses

We will compare resident-related (Specific Aim 1) and total (Specific Aim 2) rates of harmful medical errors (preventable adverse events) on the two schedules. As a secondary measure, rates of non-harmful serious medical errors (i.e., near misses) will also be compared. In an intention-to-treat analysis, rates will be compared by schedule using Poisson models with compound symmetric working correlation and robust standard errors to account for both over-dispersion and clustering by clinical center (15), and the number of patient-days at risk in each center and period included as so-called offset. The models will control for period effects and will be used to assess treatment-period interaction, a standard check with crossover trials(16).

In addition, actigraphy and sleep diaries will be used to ascertain the minimum and mean number of hours of sleep obtained per night, total sleep time, wake after sleep onset (WASO; minutes), and sleep efficiency. We will also compare performance based on results captured by the Psychomotor Vigilance Test (PVT). Specifically, we will compare the the numbers of lapses in vigilance, defined as a reaction time >500 ms, on the PVT. This Intention-to-treat comparison will be made using linear mixed models for repeated measures, with nested random effects to account for clustering within clinical center and residents<sup>12</sup>. Outcomes will be normalized as necessary; generalized linear mixed models appropriate for other outcome distributions, and/or bootstrap standard errors will be used if adequate normalization cannot be achieved. In preliminary analyses, we will assess the comparability of the residents in the intervention and control periods in terms of age, gender, post-graduate year (PGY2 vs PGY3), as well as other potential confounders of the intervention. If imbalances are found, we will conduct sensitivity analyses in which we flexibly adjust for the potential confounders.

### 1.7.2 Sample Size and Minimum Detectable Effects

Based on the Intern Sleep and Patient Safety Study, during which 2,203 patient-days were accrued under both schedules over a total of 8.5 months at a single center with 2 ICUs totaling

Serious medical errors	Resident-related rate per 1000 patient-days	MD-RRR with Scale Factor of 1.0 (2.0)	Unit rate per 1000 patient-days	MD-RRR with Scale Factor of 1.0 (2.0)
overall	136.0	8.0% (11.2%)	193.2	6.7% (9.4%)
intercepted	70.3	11.0% (15.5%)	95.1	9.5% (13.3%)
non-intercepted	44.8	13.8% (19.2%)	59.5	11.9% (16.7%)
<b>Preventable AEs</b>	<b>20.9</b>	<b>19.8% (27.5%)</b>	<b>38.6</b>	<b>14.8% (20.6%)</b>

**Figure 3, power table.** Minimum detectable relative rate reductions (MD-RRRs) detectable with 90 percent power in two-sided tests (with alpha of 5%) for serious medical errors, by sub-type of error, using Poisson models. The primary outcomes of interest, resident-related and total preventable AEs, are bolded.

20 beds, we estimate that approximately 46,080 patient-days will be accrued across the six centers in this study, each contributing an observation period of 8 months on each

schedule, with an average census of 16 patients, or 80% of an average 20 beds. Assuming that the baseline error rates per-patient day on the standard schedule are the same as those observed

in the Intern Sleep and Patient Safety Study, the new sample will provide 90% power to detect relative rate reductions (MD-RRRs) on the sleep and circadian science-based (SCS) intervention schedule as shown in Figure 3. Estimates are shown first assuming a scale factor of 1.0, corresponding to a Poisson distribution, while conservative estimates assuming an over-dispersed Poisson distribution with a scale factor of 2.0, are shown in parentheses. For overall serious medical errors, we will have 90% power to detect reductions in both resident-related and unit error rates of 7-11%; MD-RRRs for intercepted and non-intercepted medical errors will be between 9.5 and 19%. Even for the least frequent outcome but that of greatest interest, resident-related preventable AEs, we will have 90% power to detect a relative reduction of 19.8% if the distribution is Poisson, and 27.5% under our conservative assumptions about over-dispersion. The actual reductions seen in our preliminary study were larger than these thresholds in each sub-category of resident-related serious errors, including resident-related preventable adverse events. Thus, we expect to be adequately powered to draw definitive conclusions regarding the effectiveness of the *SCS schedule* intervention. In assessing interaction/period interactions, MD-RRRs will be fourfold larger than the main intervention effects. However, because residents will participate in at most one period, the potential for carryover effects is much smaller than in most crossover studies.

In addition, for sleep and work hours as well as PVT results, we estimate the expected sample of 300 residents will provide 90% power in 2-sided tests with alpha of 5% to detect standardized between-group differences of 0.30 to 0.37 standard deviations of the outcome, depending on the design effect

Outcome	MDE
Sleep hours (weekly)	1.75 / 1.92 / 2.21
Work hours (weekly)	1.39 / 1.53 / 1.76
Standardized units	0.30 / 0.32 / 0.37
<b>Figure 4, minimum effects on resident outcomes</b> detectable with 90% power in two-sided 5% tests, with design effects of 1.25/1.5/2.0.	

due to clustering within centers and residents; calculations are shown in Figure 4 for minimum detectable effects (MDEs) for sleep and work hours, based on standard deviations observed for sleep and work hours observed in the ICU pilot study conducted at Brigham and Women's Hospital. Because this pilot study did not collect data on other sleep outcomes (e.g. WASO, sleep efficiency) or the performance outcomes

(PVT), the standardized units are also shown in Figure 4. These calculations show that the study will be powered to detect small-to-moderate intervention effects on these outcomes, even if the design effect is as large as 2.

## 1.8 DATA COLLECTION AND QUALITY ASSURANCE

### 1.8.1 Data Acquisition and Transmission

The DCC will develop a front-end component for data entry and transmission. Data would be entered at remote sites on secure mobile computing devices and transmitted a minimum of once a day via secure transfer. Data received will be automatically imported into SQL tables and integrated into our standard data system. Data will be available for review/updating via the standard study website within 24-48 business hours. The DCC will create and maintain a comprehensive programmer's guide for all the data systems it provides.

### 1.8.2 Data Collection and Editing

Capturing data electronically will reduce the risk of missing data. Furthermore, edits checks may be built into the instruments to flag out of range or inconsistent data. Further custom edit

checks will be written and run on data received at the DCC. Each hour, the cumulative study data is subjected to these custom edits to ensure completeness, consistency and validity of the data. The results of the error-checking procedures are posted to the study website, which the study staff will check daily to both confirm that the DCC has successfully received all of the transmitted forms and to address errors that have been detected by the edit system. The Project Manager and other Clinical Coordinating Center (CCC) staff will be responsible for checking the daily data edits and working in conjunction with the sites to address them. This data entry/data editing process is monitored by a number of standard monitoring reports that will be available on the website. An audit trail is maintained which includes the date of change, time of change, description of data change, and the study ID of the person making the change.

The DCC will also serve as the Reading Center for the actigraphy and PVT datasets. DCC staff will perform an initial review of the files upon receipt and report any issues to the clinical site staff; later DCC staff will clean and merge the device data with the form data.

The DCC will prepare comprehensive ‘clean’ datasets for analysis, providing the analysis-ready files to the CCC and others as necessary, for statistical analysis purposes. The DCC will also ensure that any entity receiving the dataset will have a Data Use Agreement on file, signed by the appropriate institutional authority. The DCC will also be responsible for preparing a public release dataset to be housed within NHLBI’s BioLINCC (or a comparable public data repository) no later than 3 years after the end of the trial or 2 years after the main paper has been published, whichever comes first.

### **1.8.3 Data Management and Study Progress**

The study website which includes a number of data management features and reports to enable clinical sites and study investigators to monitor data collection and study progress. Data Management features include a data inventory, lists of missing forms and queries by participant ID, and tools to resolve queries and update data via the website. Reports can be custom-designed to meet study needs and could include:

- Enrollment in aggregate and by site
- Demographics in aggregate and by site
- Early Discontinuation in aggregate and by site

### **1.8.4 Staff Training**

To ensure inter-rater reliability, the physician observers and research nurses will undergo training in the detection of medical errors and adverse events prior to observing residents. The training will include evaluation of test cases designed to calibrate the observers’ assessments. At least twice during each 8 month period of data collection, for each wave of sites, the DCC will examine the rates of events by observer at each of the sites to determine if there is significant variability. Re-training of physician observers will occur as needed to ensure consistent reporting of suspected medical errors across staff and sites. Documentation of the analyses of event rates as well as the staff training will be maintained by the DCC. Staff will also be instructed on procedures for entering data into electronic data collection forms and transmitting these data to the DCC. Lastly, staff will be trained in the operation of the actigraphs as well as administration of the PVT tests.

## **1.9 PARTICIPANT RIGHTS AND CONFIDENTIALITY**

### **1.9.1 Institutional Review Board (IRB) Review**

This protocol and informed consent documents, and any subsequent modifications, will be reviewed and approved by the IRB or ethics committee responsible for oversight of each of the clinical sites, as well as the clinical and data coordinating centers.

### **1.9.2 Informed Consent Forms**

Informed Consent documents will be maintained at individual sites and coordinators must ensure that they are using an up-to-date, IRB approved version of the consent form. A signed Informed Consent form will be obtained from each participant. The Informed Consent will describe the purpose of the study, the procedures to be followed, and the risks and benefits of participation and must comply with the requirements of the study site's Institutional Review Board. A copy of the Informed Consent will be given to each participant and provision of the copy will be documented in the study participant's record. The DCC will ensure that all clinical site informed consents are consistent and include required elements.

### **1.9.3 Participant Confidentiality**

#### **1.9.3.1 Clinical Sites**

In order to protect confidentiality of the research participants as well as the patients they treat, both will be assigned a unique study identification number, which will be used to refer to them on all study forms. The list of codes linking resident-subjects' and patients' names and study IDs will be kept by each site PI on a separate password protected computer in a locked office at that site. Each site PI will be responsible for ensuring the security of these data. These identifying data will not be transmitted outside of the originating institution. Risk to patient confidentiality will likewise be minimized. All information will be de-identified at the point of data analysis.

#### **1.9.3.2 Data Coordinating Center**

The DCC follows standard operating procedures (SOPs) for computer system security to ensure the confidentiality and validity of study data. The SOPs are designed to prevent unauthorized access and limit authorized access to our computer systems and are in compliance with established standards for Information Technology Security. Our network is privately maintained, hardware fire-walled and none of the workstations or database servers can be directly addressed from outside the Local Area Network. Study website and database access requires a network domain account with appropriate account-specific permission on the database. All requests for new accounts and access to the database must be documented by a System Access Request Form signed by the project director.

## **1.10 COMMITTEES**

### **1.10.1 Steering Committee**

The Steering Committee will be responsible for all decisions concerning the scientific and technical conduct of the study. It will appoint the analysis and publications committee and

writing groups, ensuring that information from the study is disseminated in the scientific literature and at scientific meetings. The committee will be chaired by Dr. Czeisler and will include the lead site investigator from the clinical and data coordinating center and each of the clinical sites. The Steering Committee will have one in-person meeting on an annual basis, and will meet by teleconference on at least a bi-monthly basis. The Steering Committee consists of the following members:

Charles A. Czeisler, PhD, MD	Chair, PI, CCC, Brigham and Women's Hospital
Christopher P. Landrigan, MD, MPH	PI, CCC, Brigham and Women's Hospital
Katie L. Stone, PhD	PI, DCC, California Pacific Medical Center
Susan Redline, MD, MPH	Chair, Sleep Research Network
Ken Wright, PhD	PI, University of Colorado
Jeffrey Segar, MD	PI, University of Iowa
John McGuire, MD	PI, Seattle Children's Hospital
Pearl Yu, MD	PI, University of Virginia
Sue Poynter, MD	PI, University of Cincinnati
Phyllis Zee, MD, PhD	PI,
Robert Smith, PhD	Project Scientist, NHLBI

### 1.10.2 Executive Committee

An Executive Subgroup of the Steering Committee will be responsible for decisions that require attention between Steering Committee Meetings and for major financial, administrative and operational decisions. The Executive Committee will meet via teleconference at least monthly and will consist of the following members:

Charles A. Czeisler, PhD, MD	PI, CCC, Brigham and Women's Hospital
Christopher P. Landrigan, MD, MPH	PI, CCC, Brigham and Women's Hospital
Katie L. Stone, PhD	PI, DCC, California Pacific Medical Center
Robert Smith, PhD	Project Scientist, NHLBI

### 1.10.3 Principal Planning Group

A planning group comprised of the Principal Investigators and project staff of both the CCC and DCC will be responsible for the development of study documents, including the forms, protocol and operations manual, as well as the day-to-day management of the trial. The Principal Planning Group will meet via teleconference at least monthly and will consist of the following members:

Charles A. Czeisler, PhD, MD	PI, CCC, Brigham and Women's Hospital
Christopher P. Landrigan, MD, MPH	PI, CCC, Brigham and Women's Hospital
Conor O'Brien	CCC, Brigham and Women's Hospital
Katie L. Stone, PhD	PI, DCC, California Pacific Medical Center
Dana R. Kriesel, MPH	PD, DCC, California Pacific Medical Center

### 1.10.4 Working Groups

Members of the Steering Committee will form working groups to manage and oversee specific aspects of the trial. These include: (1) Data Management and Data Quality; (2) Patient Safety and PICU Quality Outcomes; (3) Sleep, Performance and Health Outcomes; and (4) Education Outcomes. Working groups will meet on an as needed basis.

### **1.10.5 Data and Safety Monitoring Board**

To monitor the study for the possibility that the intervention schedule has an adverse effect on safety, a multidisciplinary Data and Safety Monitoring Board (DSMB) comprised of financially disinterested members was appointed by NHLBI, with guidance from DCC. The board is comprised of five members with expertise in pediatric intensive care, pediatric critical care, sleep medicine, clinical trial design and biostatistics, bioethics, healthcare quality and outcomes research. The DSMB will monitor the quality and integrity of the data emerging from the proposed study; assess the adequacy of recruitment, compliance, follow-up and other aspects of study execution; and review interim analyses of the major outcomes of the trial to identify safety issues and make periodic recommendations on whether to continue, modify, or terminate the study. The DSMB will be an advisory board to NHLBI and the Steering Committee. The DSMB will work under a Charter that will be developed by the DCC, working in tandem with NHLBI. The DCC will support the DSMB by preparing interim reports for review at DSMB meetings; and by organizing scheduled and ad hoc meetings of the DSMB as needed. Please see the DSMB Charter for more details.

### **1.11 CONFLICT OF INTEREST**

The DCC will be responsible for surveying the key personnel at each study site on an annual basis regarding any conflicts of interest that may have arisen. The Executive Committee will review the results of these annual surveys and determine if any action is necessary.

**Modifications to the original ROSTERS protocol:**

Section 1.1.3 Aim 3: Assessment of motor vehicle crashes was changed from Johns Drowsiness Score to drive diaries and data gathered on the End of Rotation Survey.

Section 1.5, Study Procedures. Data collection with Optalert was deleted.

Section 1.5.3, Identification of patient risk factors. Severity of illness was changed from assessment by PRISM scores to use of ICD-9 codes.

Section 1.5.5.1, Optalert. This section was deleted because the Optalert was not used to assess driving safety.

Section 2.5.5.2, PVT. The measurement of alertness via the Karolinska Sleepiness Scale (KSS), before and after each PVT test, was added.

Section 1.5.6.2, Educational measures. The optional enrollment of residents in OpenPediatrics was added.

Section 1.6.2, Resident safety. This section was added at the request of the Data and Safety Monitoring Board (DSMB).

Section 1.7, Statistical considerations. Information regarding the analysis of Optalert data was removed.

Section 1.8.4, Staff training. This additional information was added regarding the reliability of the detection of medical errors as follows: To ensure inter-rater reliability, the physician observers and research nurses will undergo training in the detection of medical errors and adverse events prior to observing residents. The training will include evaluation of test cases designed to calibrate the observers' assessments. At least twice during each 8 month period of data collection, for each wave of sites, the DCC will examine the rates of events by observer at each of the sites to determine if there is significant variability. Re-training of physician observers will occur as needed to ensure consistent reporting of suspected medical errors across staff and sites. Documentation of the analyses of event rates as well as the staff training will be maintained by the DCC.

Section 1.10.1, Steering Committee. Changes in membership were noted.

Section 1.10.2, Executive Committee. Changes in membership were noted.

Section 1.10.3, Principal Planning Group. Changes in membership were noted.

Section 1.10.5, Data and Safety Monitoring Board. This information was added: . The board is comprised of five members with expertise in pediatric intensive care, pediatric critical care, sleep medicine, clinical trial design and biostatistics, bioethics, healthcare quality and outcomes research.

**ROSTERS Statistical Analysis Plan**

*Definition of medical error outcomes.* The primary outcome of the study will be resident-related harmful medical errors (preventable adverse events) and other medical errors (near misses), as determined by the adjudication process specified in the protocol. In brief, all potential medical errors and adverse events reported by the study sites will be reviewed by two site investigators, blinded to the site of origin. Physician reviewers will classify events as: (1) adverse event / harm; (2) intercepted near misses with potential for harm; (3) non-intercepted near miss with potential for harm; (4) error with little or no potential for harm; and (5) exclusion. If an event is classified as “adverse event / harm”, the reviewers will then classify the level of harm and indicate to what extent the incident was preventable. Discordant reviews will be resolved by teleconference or assigned to a 3<sup>rd</sup> reviewer, as needed. Total ICU-wide preventable adverse events and near misses will be secondary outcomes.

*Definition of secondary sleep outcomes.* Actigraphy data and sleep diaries will be used to ascertain the minimum and mean 24-hour sleep times. If there is sufficient data collected, we will also measure performance on the Johns Drowsiness Score (JDS), based on results captured by Optalert. Specifically, we will calculate the time-weighted average JDS score for each commute; the proportion of the shift minutes spent with a JDS score above 4.5, the cutoff for impairment. Additional outcomes include variables derived from the Psychomotor Vigilance Test (PVT), including the numbers of lapses in vigilance, defined as a reaction time >500 ms, on the PVT.

*Definition of safety outcomes.* Safety outcomes consist of motor vehicle accidents (MVAs) and near misses, drowsy driving, needle sticks and other body fluid exposures, suicide ideation and resident SAEs. MVAs, near misses, and drowsy driving are captured both in the End of Rotation Survey (completed by all enrolled residents) and in the Drive Diary (completed by residents who drive to and from the hospital). Information about needle sticks, body fluid exposures, depression, and suicidal ideation are captured in the End of Rotation Survey as well. Resident SAEs are reported as they occur.

*Preliminary analyses.* Preliminary analyses include ongoing efforts to check and clean the data. The electronic data collection forms are designed to minimize missing data and skip pattern errors, by requiring responses to questions and only displaying sub-questions, based on responses to parent questions. A series of edit checks are run daily to detect data inconsistencies (eg, inconsistent dates). Furthermore, additional checks are run on the entire data set to check for inconsistencies or errors across forms. The Resident Sleep/Work and Drive Diary data is reviewed a few times per week for errors and missing data. Diary findings are communicated to the sites, who confirm any diary changes or additions with Residents.

Objectively measured sleep data will be collected using an actigraph (Motionlogger-L model; Ambulatory Monitoring Inc, Ardsley, NY). Actigraph files will be processed at the DCC using manufacturer-specific software (Action-W2 software, version 2.7.2288). Participating residents will complete sleep diaries for the time period they wore the actigraph, which includes time into and time out of bed and times the actigraph was removed. This information will be used in editing the actigraphy data files to set intervals for when the participant was in bed trying to sleep, and to delete time when the actigraph was removed. Inter-scorer reliability for editing the actigraphy data files has been previously found to be high in our group (intra-class coefficient = 0.95). (Blackwell 2005) Sleep-scoring algorithms available in the software will be used to determine sleep from wake times. (Cole 1992, Girardin 2001) These algorithms calculate a moving average, which takes into account the activity levels immediately prior to and after the current minute, to determine if the time point should be coded as sleep or wake. The summary measure of total sleep time across a 24-hr period will reflect data averaged over all 24-hr periods the device was worn in order to obtain a more representative characterization of usual sleep patterns during the rotation.

Once we have needed data from the site, we will determine whether the observers report similar rates of suspected events within centers, by schedule and period. We will also examine rates of discordance between adjudicators periodically to identify and address potential problems.

*Assessment of balance between schedules.* To assess balance of the treatment and control samples, we will compare resident characteristics by schedule, stratified by clinical center, assessing within-center and overall differences, as well as center by schedule interaction. These checks will use linear, logistic, and other generalized linear models as appropriate to the distribution of each of the baseline covariates. Baseline variables to be considered will include resident age, gender, race, post-graduate year (PGY2 vs PGY3), body mass index, lifestyle factors (including smoking, alcohol use and caffeine intake), physical activity and medical history (including sleep apnea).

*Analysis of medical error outcomes.* Rates per 1000 patient-days of the medical error outcomes will be compared by schedule using log-link Poisson models, with clinical center, period, and schedule as fixed effects, robust standard errors to account for potential over-dispersion, and the log of the number of patient-days at risk as an offset. Outcome events and total patient days will be summed over each study period for each clinical site, omitting missed observer shifts, based on reports of the missed shifts and corresponding patient censuses from the sites. We will also assess treatment-period interaction, a standard check with crossover trials.

*Analysis of secondary outcomes.* Comparisons of actigraphic outcomes will be made using regression models for summary outcomes constructed for each resident over their entire period, again controlling for clinical center and period. These outcomes will be normalized as necessary; generalized linear models appropriate for other outcome distributions, and/or bootstrap standard errors will be used if adequate normalization cannot be achieved.

*Analyses of safety outcomes.* Numbers of resident needle sticks, fluid exposures, MVAs, MVA near misses, MVAs with injuries, as well as numbers of each reported as related to fatigue or drowsy driving, will be compared by schedule using the methods proposed above for harmful medical errors. Offsets will be calculated as the numbers of resident days determined using work and drive diaries. Because MVA injuries are expected to be too uncommon for meaningful statistical comparison, they will be presented using individual narrative descriptions.

*Mediation of the effects schedule on medical errors by sleep measures.* We will assess mediation of the effects of schedule on resident-related harmful medical errors by the effects of schedule on 24-hour sleep times and PVT scores. We will use simulation methods (Imai 2010) as implemented in the *mediation* package in R [R Foundation for Statistical Computing, Vienna].

*Sensitivity analyses.* Two sensitivity analyses will be performed.

- If imbalances are found between schedules in our preliminary assessment, described above, we will conduct sensitivity analyses, both for primary and secondary outcomes, in which we flexibly adjust for the potential confounders that are associated at  $P < 0.1$  with schedule either overall or within at least one center. These will include analyses adjusting for the number of residents with sleep disordered breathing, including sleep apnea; additional sensitivity analysis of the secondary outcomes will exclude these residents.
- If the numbers of missed observer shifts are imbalanced by schedule, we will conduct sensitivity analyses using multiple imputation of resident and total medical errors during unobserved shifts under both standard missing at random (MAR) and also plausible missing not at random (MNAR) assumptions. Specific MNAR scenarios will include doubling of the error rates during unobserved shifts in both schedules, first simultaneously, then one at a time.

## Stopping Guidelines

Stopping for benefit and harm. The DSMB Guidelines for recommending continuation, modification, or stopping the study will explicitly include consideration of both statistical and non-statistical issues and include the possibilities of early stopping for benefit, stopping early for harm, stopping for futility, and modification of protocol.

Primary outcome for assessing benefit and harm. We propose to use the numbers of resident-related harmful medical errors as the primary outcome for both benefit and harm. Additional considerations for stopping for harm could include serious adverse events among residents, including needle sticks, fluid exposures, and MVAs.

Rules for stopping. We propose to use Lan-DeMets methods (Lan 1983) to define symmetric stopping boundaries; the DSMB may decide to use a more liberal rule for stopping for harm or to allocate type-I error differentially to efficacy and harm. We will use an alpha spending function resulting in boundaries similar to O'Brien-Fleming, making it difficult to stop early but inducing minimal shrinkage in the alpha for the end-of-trial analysis. We propose two interim analyses of treatment effects on the primary benefit/harm endpoint. The first analysis will occur when Sites 1 and 2 will have completed both schedules; and the second when Sites 1-4 will have completed both schedules. To aid in decision making, partial data will be provided for sites 3 and 4 at the first look, as well as for sites 5 and 6 at the second, but not included in the interim analysis; the rationale for these exclusions is that between-site differences would confound schedule if the sites contributing outcomes for only one schedule were included. With an overall type-I error rate of 5% allocated equally to benefit and harm, critical values of the Z-statistics at the first, second, and final analyses will be 2.67, 2.32, and 2.03 respectively, corresponding to 2-sided p-values of 0.008, 0.021, and 0.043. The DSMB will consider stopping the study early for efficacy or safety if the absolute Z-statistic at the first and second interim analysis exceeds the boundary values of 2.67 and 2.32 respectively.

Stopping for futility. The decision to stop for futility will be informed using simulations of conditional power, given the current data, to detect a 10% reduction in overall resident-related medical errors, and a 25% reduction in resident-related preventable AEs (Lan 1982; Halperin 1982). These analyses entail no inflation of the overall type-I error rate, and will be conducted in conjunction with the two interim analyses of benefit/harm. The DSMB will consider stopping the study for futility if estimated conditional power to detect the specified treatment effects falls below 50% for both outcomes. These decisions are complex and the guidelines may be further developed by the DSMB and NHLBI, with the assistance of the DCC.

## Interim Analyses

An unblinded statistical analyst at the DCC will analyze the major endpoints at the time points specified above, and reports will be prepared for presentation to the DSMB. Except for designated NHLBI and DCC staff, all investigators and staff will remain blinded to interim results. Interim reports will be derived from the database as it exists on pre-specified dates, and full copies of the database at the time of each interim analysis will be archived. The interim analysis tables will be the same as the tables used in the open and closed sessions of the DSMB meetings, but results will be stratified by sites and include P-values. Please see a list of the tables below:

### Interim Analysis Tables

#### Study Progress

Table 1: Summary of Residents Declined Participation

Table 2: Enrollment Status by Schedule, Wave and Site

Figure 1: Cumulative Enrollment by Month, by Site/Schedule

Table 3: Patient Days by Schedule, Wave and Site

**Descriptives**

Table 4: Summary of Disposition and Follow-up by Schedule

Table 5: Summary of Demographic and Baseline Characteristics by Schedule

**Primary Outcome**

Table 6: Resident Incidents Occurring During Rotation

Table 7: Patient Incidents Occurring During Rotation

**Secondary Outcomes**

Table 8: Summary of Quality of Work Experienced by Schedule

Table 9: Summary of Depression by Schedule

Table 9: Summary of Self-Reported Sleepiness by Schedule

**Modifications to the original ROSTERS statistical analysis plan:**

Additional analysis were requested by the DSMB as follows:

- Requested at April 2016 meeting. Show medical errors results broken down by severity of error.
- Requested at November 2016 meeting. Adjust models with medical errors outcomes by patient risk score.
